

Hartford City Special Study

In response to concerns regarding the Hartford Iron and Metal facility (HI&M) in Hartford City, Indiana, including a letter sent to the Indiana Department of Environmental Management (IDEM) by the Blackford County Concerned Citizens (BCCC), the Office of Air Quality (OAQ) conducted a special monitoring study near the facility from May 2020 through August 2020. The BCCC was concerned that particulates, or more specifically metals emissions, from the HI&M operations were impacting air quality in the surrounding area. IDEM determined that a short-term monitoring project near the facility would help determine what concentrations of metals were in the air.

Monitoring Project

The monitoring project was designed to collect information regarding ambient metals concentrations over a four-month period. A suitable monitoring location was procured approximately 250 feet to the east of the facility in question. Figure 1 shows the area around the facility and identifies the monitoring location.

Total suspended particulate (TSP) samples were to be collected and analyzed for the metals listed below.

| | | | | | | | |
|-----------|-----------|-----------|--------|------------|-----------|----------|----------|
| Aluminum | Antimony | Arsenic | Barium | Bromine | Cadmium | Calcium | Cerium |
| Cesium | Chlorine | Chromium | Cobalt | Copper | Indium | Iron | Lead |
| Magnesium | Manganese | Nickel | | Phosphorus | Potassium | Rubidium | Selenium |
| Silver | Sodium | Strontium | Sulfur | Tin | | Titanium | Vanadium |
| Zirconium | | | | | | | Zinc |

Hexavalent Chromium

The metals considered Hazardous Air Pollutants (HAPS) by USEPA are marked yellow.

Sampling Procedure

Two intermittent samplers were used to collect the samples for analysis. A Thermo Partisol 2025b sampler with a TSP inlet head was used to collect a 24 hour sample every six days. These 47mm filters were sent to UC Davis for analysis by X-ray fluorescence spectroscopy (XRF) for 33 metals. UC Davis is contracted by USEPA to analyze the PM2.5 speciation filters collected across the country. A PUF (polyurethane foam) sampler was used to collect the samples to be analyzed by Eastern Research Group (ERG) for Hexavalent Chromium (Cr6+) using their SOP ERG-MOR-063. These 24-hour samples were collected every 12 days. ERG is the lab contracted by USEPA to analyze these types of samples and provide support to various monitoring projects.

Sampling of the 33 metals began on May 3rd, 2020 and the Cr6+ sampling began on May 9th, 2020. The last samples were collected on August 25th, 2020. All samples collected were valid and sent to the appropriate laboratory according to the protocols established by each lab.

Results

Table 1 lists the raw data values for the individual samples collected at the Hartford City Site. All values were very low, and many samples measured 0.000 ug/m³ or below the minimum detection limit (MDL) for the individual parameter.

Past Study Comparisons

In order to put some perspective on the level of the concentrations observed at Hartford City, the data collected during this study was compared to other past monitoring efforts which had collected metals data. The comparison of data is summarized in Table 2.

Typically three different particle sizes can be collected and analyzed; TSP (Total Suspended Particulates, generally all particulate matter less than 100 microns in size), PM10 (Particulate Matter less than 10 microns in size), and PM2.5 (Particulate Matter less than 2.5 microns in size, or fine particulate).

Hartford City and Kokomo collected TSP samples. The School Air Toxics Study and the SW Indy Study collected metals in the PM10 fraction. And PM2.5 samples are collected and analyzed as part of the PM2.5 Speciation Trends Network.

The Hartford City and Kokomo monitoring locations were sited very near potential particulate sources. One could expect higher concentrations of specific metals from the source operations. The School Air Toxics Study collected samples at schools which had major sources located from about ¼ mile to several miles away. The sites in the SW Indy Study were located in an area with multiple sources located near the monitoring locations. The PM2.5 Speciation monitoring sites are generally located in areas not influenced by a specific source or sources.

When comparing the data from the different sites, most of the average values collected at the Hartford City site were close to or below the values collected at other sites and studies. The individual parameter graphs are in Figure 2 through Figure 10.

Conclusion

The concentrations of the metals collected during the study are very low and do not rise to levels of concern. The values are often below the detection limit of the analytical process for several of the metals. The concentrations were consistent with other values collected across Indiana in a variety monitoring programs.
